Individual Income Tax Gap

Tax Year 1999

WARNING: While attempting to update this study, we discovered that its methodology was flawed. We no longer believe that the portions of the tax gap estimate derived from analysis of Census data are correct. **Please do not rely on this report's estimates of the total tax gap or its components.**

The error was in misinterpreting the way the Census “top-codes” some reported incomes. The report assumed, incorrectly, that “incomes that exceed a threshold amount (which depends on the particular type of income) are listed as *equal to the threshold*” (page 10, emphasis added). This is not true. Instead, the Census sets top-coded incomes *equal to the average income of all who exceed the threshold*.

When top-coding is interpreted correctly, the approach taken in this study results in a *negative* tax gap in both 1999 and 2002. Total income reported to the Census is slightly *less* than what is reported to the IRS, so Census data cannot provide an accurate estimate of underreported income.

This report will remain on our website because we believe this is the most effective way to communicate this error to those who may look for the report in the future.

Acknowledgements

In addition to the contributions to this study that were made by more than a few people at the Minnesota Department of Revenue, we would like to acknowledge the considerable assistance of Tom Gillaspay, Minnesota State Demographer; John Peloquin, Minnesota Department of Finance; Aamir Gangji, intern, University of Minnesota; and Clyde Thurston and Alan Plumley, Internal Revenue Service.

Introduction and Executive Summary

A tax gap is the difference between the total tax actually collected and the amount that would have been collected if all those required to pay had paid the correct amount of tax. This report investigates the income tax gap for Minnesota in 1999. The research is intended not only to supply an estimate of the 1999 gap, but also to develop and apply a methodology that can be used on an ongoing basis to calculate income tax gap amounts over time.

There are at least two reasons to investigate a tax gap. Noncompliance costs the state revenue that could be used to provide services to Minnesotans. It also undermines the equity and efficiency of the tax system by increasing administrative costs and by unfairly shifting the tax burden to those who do comply.

The income tax gap consists of two parts: tax amounts due from those who did not file a tax return (nonfilers,) and the additional tax amounts that should have been paid by those who did file, but reported less than their full tax liability (underreporters).

In 1999, Minnesota's total income tax gap is estimated to have been almost \$604 million, of which nearly \$125 million is attributable to nonfilers and more than \$ 479 million to underreporting.

Amounts in figures and tables may not equal totals due to rounding.

Minnesota Individual Income Tax As Percent of Total Tax Due Calendar Year 1999 (\$ Millions)

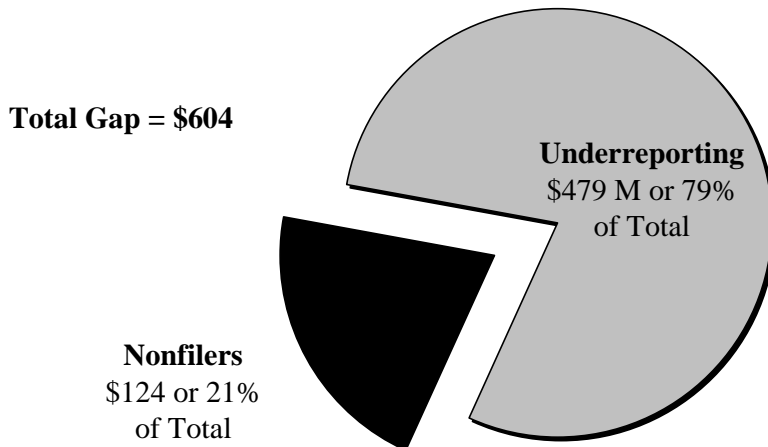

Nearly 670,000 possible filers (individuals and married couples) were responsible for this shortfall. We estimate that 314,000 returns should have been filed that were not, and another 356,000 returns underreported.

Underreporting as used in this study is a net concept. Some people underreport income and tax liability, and a smaller number overreport. Figures given in this study refer to the difference between the two. Also, the number of nonfilers includes those who received a payment statement such as a W-2 and who would have been entitled to a refund of amounts withheld had they filed a return.

The study also distinguishes between the tax gap attributable to wage income and that attributable to all other income (nonwage income). Nonwage income is primarily business income from sole proprietorships, investment income and rents. It is likely that the degree of tax compliance varies with the type of income received. For income types such as wages, where there is independent documentation of amounts received, the degree of compliance is likely to be higher than for income types, such as farm income or self-employment income, where no such record exists, and indeed, that pattern does appear in available data.

The results described here depend in large part on data from the 2000 census. We anticipate that data for the same variables will be available in noncensus years from the American Community Survey, an annual survey project recently implemented by the Bureau of the Census.

Methodology

Summary of Approach

We compute the total income tax that would have been generated in Minnesota if everyone who should have filed did so, and if all filers reported the correct tax liability. This overall tax liability is calculated using data from the 2000 census and from the 1999 income tax sample (described in the following section). From that figure, we subtract the amount actually paid on a voluntary basis. What remains is the income tax gap. The gap consists of two parts: that attributable to nonfiling, and that attributable to underreporting. The portion attributable to nonfiling is estimated from various data sources described later. The portion attributable to underreporting is the remainder after the nonfiler tax gap is subtracted from the total income tax gap.

We divided the tax liability into two parts: that attributable to wage income and that attributable to all other income. This was done for all components of the analysis: the expected tax liability, assuming full compliance; the income tax actually received; the amounts due from nonfilers; and the amounts due from underreporters. Where both wage and nonwage income figures were available, they were used to determine the fractional share of tax allocated to each. For the W-2 file (discussed below), we assumed that all income is wage income.

There are also persons for whom no tax administrative information at all is available, but that the census data indicates should have filed. These “invisibles” are discussed below. For such persons, the assumption is that all income is nonwage.

Underreported wage income was assumed to be 0.5 percent of all underreported income, based on the most current information available.

Census data allows an estimate of the total number of filers assuming full compliance. Of course, we also have the total number of those who did actually file. The number of nonfilers was estimated from various data sources described later. The number of underreporters is based on IRS Taxpayer Compliance Measurement Program data.

Data

The study used four sources of data.

2000 Census. Detailed information about Minnesotans is available from the 2000 United States census. This study used the 1 percent Public Use Microdata Sample (PUMS), a random sample of 1 percent of Minnesota households (with personal identifying information removed). The PUMS sample contains information on all individuals in a given household. This includes age, family structure, relationship to the head of household, income by type, educational status and many other variables. From this, it is possible to derive an estimate of the number of income tax returns that should have been filed by the individuals in each of the sample households, and hence the number that

should have been filed by all Minnesota residents. It is also possible to distribute those returns by income level.

Census income categories are more aggregated, and thus less specific, than tax income categories. The census collects information on six kinds of income that are taxable in whole or in part: wages and salary; self-employment (including farming); unearned income, including interest, dividends and rents; social security; retirement other than social security; and a miscellaneous category that includes taxable items such as unemployment compensation and nontaxable income such as child support. The census also collects information on two wholly nontaxable income categories: supplemental security income (SSI) and public assistance.

Income Types for Gap Estimates

<u>Census Categories</u>	<u>Form 1040</u>
➤ Wage and salary	Wage and salary
➤ Self-employment income	Business income Farm income
➤ Interest, dividends, net rental income, royalties, income from trusts and estates	Taxable interest Tax-exempt interest Dividends Schedule E income
➤ Social security retirement	Social security
➤ Supplemental security (SSI)	Not taxable
➤ Public assistance	Not taxable
➤ Pensions (other than social security)	IRA distributions Pensions Workers Comp. (nontaxable)
➤ Other (e.g., VA payments, unemployment, child support, alimony) if received periodically	Alimony Unemployment Other income Nontaxable Income
Census does not capture episodic or one-time income such as capital gains.	Capital gains Other gains

Census income information is not sufficient to allow direct calculation of income tax liability for each return for three reasons:

1. The census definition of income includes only items received periodically, such as wages and interest. It omits income received episodically, such as capital gains.
2. Census income is aggregated into eight categories. While for some of these categories all the income is either taxable or not taxable, for others the two are mixed and it is difficult to separate the two. For example, the census category that includes interest includes both taxable and nontaxable interest.
3. Income amounts are topcoded to prevent individuals from being identified in the sample; that is, incomes that exceed a threshold amount (which depends on the particular type of income) are listed as equal to the threshold. Therefore it is not possible to use census data to replicate tax returns for high-income persons.

1999 income tax sample. A second source of information is a sample of resident income tax returns filed with the Minnesota Department of Revenue for tax year 1999. This database includes detailed information about income types, filing status and tax liability.

Various IRS data sets. A third source is information concerning those who did not file a Minnesota tax return for 1999. The data falls into two groups, each with two subsets.

The first group of records consists of those who filed a 1999 federal tax return. This group was divided into those with taxable incomes less than \$5,000 and those with taxable income greater than that amount, which corresponds to the way tax compliance efforts are organized. The department focuses its tax compliance programs on those with taxable incomes greater than \$5,000.

The second group consists of those who did not file a federal return but for whom income data was available from payer information supplied to the IRS (such as wages reported by employers or interest reported by financial institutions). These federal nonfilers were further divided into those with gross income between \$10,000 and \$20,000, and those with gross income greater than \$20,000. This division corresponds to the department's compliance efforts. For those with gross income greater than \$20,000, additional information had often been developed. It was assumed that those with gross income below \$10,000 were unlikely to be required to file, so no effort was made to analyze those cases.

Counts of underreporters, and distribution by income level, were based on 1988 data from the Taxpayer Compliance Measurement Program of the Internal Revenue Service.

W-2 data. The final source is wages paid and amounts withheld as reported by employers directly to the Minnesota Department of Revenue. This is not a complete data set; it includes only those employers who report information electronically. Of the records in the W-2 file, most had sufficient information to make it possible to determine which individuals had filed an income tax return or which had not. (Some records had personal identifiers that were either missing or incomplete, and these could not be

assigned to either category.) To estimate how many nonfilers were missing from the electronic W-2 data, the number of W-2 records in this file identified as filers was compared to the number of W-2s in the income tax sample (blown up to represent the entire population of filers). For 1999, we estimate that employers reported about 52 percent of W-2s for filers electronically. This same percentage was applied to W-2s for nonfilers, and the number of nonfilers obtained from the W-2 file was scaled up proportionately.

While the W-2 file is a source of nonfiler information, it must be noted that taxes have for the most part been withheld from the associated wages. Many of these individuals might have been due refunds had they filed. Some may owe taxes, also. Therefore, the potentially recoverable income tax gap is less than the total gap discussed in the analysis.

Computations

To create an estimate of the total income tax liability for Minnesota residents, the income tax sample was modified to resemble the census income data as much as possible. Income tax sample incomes were topcoded in the same manner as census incomes, and capital gains were dropped. The ratio of census total income to the adjusted income tax sample total income was calculated, and that ratio was used to scale up the tax liability for each income interval in the income tax sample. The result is an estimate of what the tax liability would be (for each income range) if everyone in the census who was required to do so had filed and paid the correct tax.

This approach assumes that when people fill out the income portion of their census forms they use tax concepts of income. Also implicit is the assumption that income types not asked about in the census and therefore unobserved for census respondents (capital gains, for example) are similar in magnitude and distribution to those of the sample returns.

The amount actually paid voluntarily, of course, comes from the income tax sample (which accurately reflects the filer population). The difference between the two, at each income range level, defines the total income tax gap.

Calculation of tax owed by nonfilers came from analyzing the IRS and W-2 data sets. For nonfilers who had filed federal tax returns, Minnesota taxable income, and then Minnesota tax liability, was calculated. For those who had not filed a federal return and for whom additional information had not been generated through the compliance process, we made assumptions that were sufficient to allow a tax liability to be calculated. These assumptions were the same as those made in creating a commissioner-filed return: the filer is single, with one personal exemption, and claims the standard deduction.

The invisibles. The census data provided an estimate of the total number of taxpayers who should have filed. After subtracting those who did file and the nonfilers who could be identified from other data sources, we were left with a shortfall of about 34,000 returns that were not filed and for which no income or tax data exist. These are the invisibles. Since they did not appear on the W-2 file, we assumed that all income for the invisibles is nonwage income.

Tax gap and other data presented in this study are divided into two parts: that attributable to wage income and that attributable to all other income. Where sufficient data exists, the fraction allocated to each is determined by the relative magnitude of each kind of income. In other cases, only one kind of income is known, and there (as in the case of nonfilers from the W-2 file) the entire tax amount is allocated to that type of income.

Evaluating the Results

As is apparent from the discussion in this report, measuring the tax gap is difficult. Yet a comparison of the gap amount in this report to a gap value derived differently implies some degree of confidence in the results given here.

A comparison of national income amounts by type between values computed by the Bureau of Economic Analysis and aggregate Internal Revenue Service incomes by type shows a national income shortfall – gap – of roughly \$707 billion for 1999. If Minnesota accounts for 2 percent of this total then there is an income gap here of \$14 billion. By comparison our estimated tax gap of \$604 million implies an income gap here of perhaps \$11 billion, assuming an average tax rate of 5.5 percent.

Narrowing the Gap

The most recent estimate of Minnesota's individual income tax gap, for fiscal year 1990, was \$457 million, compared to the estimate for 1999 of \$604 million, a difference of \$147 million. This does not mean that the gap has grown by that amount, however. The gap amounts are not exactly comparable, for several reasons. The previous study used a methodology quite different from that employed here. In the earlier report, the tax gap was estimated by assuming that nonfiler and underreporting percentages were the same in Minnesota as for federal income taxes. Federal data were available from the IRS Taxpayer Compliance Measurement Program (TCMP) for tax year 1987. The individual income tax gap at the federal level was 15.9 percent of individual tax receipts, and that percentage was applied to Minnesota collections data as reported by the Bureau of the Census. This approach would not have been desirable for the present study because the TCMP program ended in 1987.

As a result of the difference in methodology, the 1999 figure in this report is the gap before income tax credits, while the 1990 figure is after credits. The 1990 figure incorporates only "known" nonfilers (based on audit information), while the 1999 figure includes the universe of nonfilers.

Finally, during the intervening years the economy has grown considerably, while income tax rates were reduced significantly, both of which would act to reduce the average gap per dollar of state income.

Improving compliance. Tax administrators try various methods to bring about increased tax compliance. They include both carrot and stick approaches: increasing audit rates, increasing penalties for noncompliance, increasing administrative contact between tax agencies and taxpayers, making collections procedures or agencies more visible, offering tax amnesty programs, offering taxpayer education sessions, and making tax policy changes.

During the last four years, the Minnesota Department of Revenue has done the following to promote income tax compliance:

- Added 34 field audit positions through Legislative initiatives.
 - ◆ Grew from 19 to 53 since 2000.
 - ◆ Audit assessments grew from \$19 million in FY 03 to \$40 million in FY 04.
- Expanded our computerized IRS data matching programs.
 - ◆ More than 30,000 computer-generated deficiency notices will be generated by the end of August.
- Redirected 12 telephone assistance positions to office audits.
- Greatly expanded our “early audit” and fraud detection programs.
 - ◆ Reviewed more than 14,000 returns this year before releasing any refunds.
 - ◆ Reduced refunds by \$42.7 million in calendar years 2002 and 2003.
- Greatly expanded our nonfiler discovery program through automation.
 - ◆ Quintupled the case resolutions with half the staff.
 - ◆ Since October 2000, more than 47,000 nonfiler cases have been resolved, \$160 million assessed, and more than \$40 million collected.
 - ◆ More than 50 percent of the resolved taxpayers remain in compliance.
- Added positions in the Collection Division to collect income taxes.
- Heightened public awareness through substantial media exposure of tax evasion charges, convictions or guilty pleas.

Looking forward, our plans for future compliance initiatives are to:

- Continue to expand our electronic fraud detection system.
- Continue to pursue fraudulent tax preparers both civilly and criminally.
- Expand our outreach and education programs for immigrant communities.
- Consider the impact of statewide licensing of tax preparers.
- Use technology in discovery operations (business intelligence software, geographic information systems, and warehouse development).

Appendix: Nonfiler Detailed Tables

**Minnesota Individual Income Tax Gap
Tax Year 1999
(\$1,000s)**

Federal Return: Taxable Income < \$5,000				
Income Range	Tax Liability	Wage	Nonwage	Count
< \$4,999	\$2,528	\$416	\$1,561	619

Glossary

census – the decennial collection of information of various kinds on Americans; as used in this study, refers to information about Minnesotans.

commissioner-filed return – a return prepared by the Minnesota Department of Revenue for a nonfiler, based on information available to the department. Usually this comprises one or more income amounts. A set of assumptions necessary to complete a return is used: the taxpayer is single, has one personal exemption, and uses the standard deduction.

filers – those who file a return.

income tax sample – a stratified random sample of Minnesota tax returns collected and prepared by the Minnesota Department of Revenue.

invisibles – nonfilers for whom no data sources such as W-2s or federal information exist.

nonfilers – those who are liable for tax but do not file a return or pay tax, or people who need to file to claim a refund.

nonwage income – all income other than wage income. Includes, for example, net income from a business (sole proprietorship), interest on a bank account, or income from rental property.

PUMS – acronym for Public Use Microdata Sample; a 1 percent or 5 percent sample of census information about Minnesotans (with personal identifying information removed).

tax compliance – behavior that results in the correct amount of tax being reported and paid.

tax gap – the difference between what revenue would be collected from a tax if everyone paid the correct amount, and what is actually collected. Does not include illegal activity except to the extent it is reported on a tax return, or is included in response to census questions concerning income.

topcode – a technique to prevent individuals from being identified in a sample; values in excess of a specified amount for a particular variable are reported as equal to that amount.

underreporters – those who file a return but report and pay less tax than is due.

voluntary tax – a tax amount correctly calculated and reported on a return filed at the initiative of the taxpayer.

W-2 – IRS form on which wage income is reported.

wage income – income from wages and salaries.
